Abstract

In this study, we modelled the spread of disease in Manchester, comparing this to Monte-Carlo simulations and pre-lockdown Covid data. This model assumed no lockdowns were put in place, blah blah blah. Our study successfully/unsuccessfully modelled spatial disease spread. Could be improved by considering x y z.

Introduction

Modelling disease spread is difficult, want better predicitions so governments can make plans.

When first thinking about this problem, we considered x y z.

Theory

By thinking really really hard we thought of the equation:

$$E = mc^2 + AI. \tag{1}$$

Results: Simulation vs Data

Put things here

Results: Figures

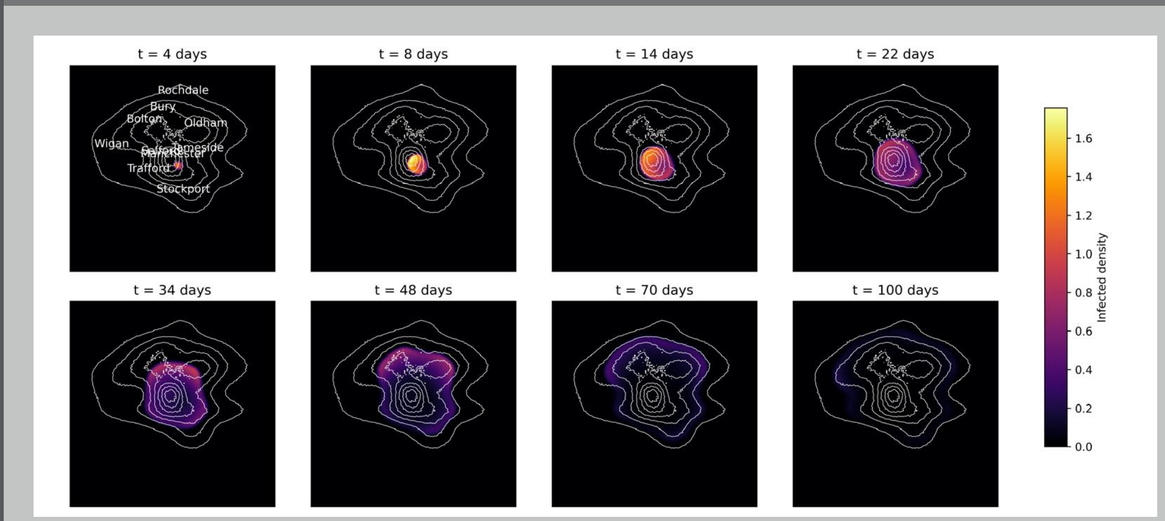

Figure 1: Disease spreading over time in Greater Manchester.

Discussion

This worked/didn't work. This will for sure effect something.

Conclusions

We things out ig.
